

# Spark Machine Learning

CMPT 732, Fall 2017

## Recap: Machine Learning

Consider a family of functions or models  $y(x; \theta)$  that map input columns (*features*  $x$ ) to an output column (*prediction*  $y$ ).

Learning a model means to find a function with *parameters*  $\theta$  that minimizes a certain measure of error or loss between prediction  $y$  and given target *labels*  $t$ .

For discrete outputs  $y \in \{\text{apples, oranges, ...}\}$  this is called *classification* or *clustering* (if no labels are given). For continuous  $y$  (e.g. floating point) this is called *regression*.

## Spark ML

- **ML Algorithms:** common learning algorithms
- **Featurization:** feature extraction, transformation, dimensionality reduction, and selection
- **Pipelines:** tools for constructing, evaluating, and tuning ML Pipelines
- **Persistence:** save and load algorithms, models, and Pipelines
- **Utilities:** linear algebra, statistics, data handling

## Pipeline Components

- **DataFrame:** from Spark SQL with columns storing text, feature vectors, true labels, and predictions
- **Transformer:** maps one DataFrame to another, e.g., feature extractors, or model predictions
- **Estimator:** E.g., a learning algorithm that trains on a DataFrame and produces a model (Transformer)
- **Pipeline:** chains multiple Transformers and Estimators together
- **Parameter:** common API for Transformers and Estimators

## Example

Check out the [Logistic Regression](#) example.

## Feature Transformers

Let's go over [the Feature Transformer list](#).

## Pipeline as Estimator

Specifies sequence of stages that are either Transformers or Estimators.

The picture shows a Pipeline at *training time*.

## PipelineModel

`Pipeline.fit()` produces a model that is used during *test time*.
